

PHYS 4 Exam 5 Cheat Sheet (with L<sup>A</sup>T<sub>E</sub>X)  
Angular Kinematics

$$\theta = \frac{S}{r}; \omega = \frac{d\theta}{dt}; \alpha = \frac{d^2\theta}{dt^2}; (1) \omega(t) = \omega_0 + \alpha t$$

$$(2) \theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2; (3) \omega^2 = \omega_0^2 + 2\alpha\Delta\theta$$

$$v_t = \omega r; a_t = \alpha r; a_c = \omega r^2; T = \frac{2\pi}{\omega}$$

Electric Fields and Forces

$$e = 1.602 \times 10^{-19} \text{C}; \epsilon_0 = 8.85 \times 10^{-12} \frac{\text{C}^2}{\text{Nm}^2}$$

$$k = 8.99 \times 10^9 \frac{\text{Nm}^2}{\text{C}^2} = \frac{1}{4\pi\epsilon_0}$$

$$\vec{F} = \frac{kq_1q_2}{r^2}\hat{r} = \frac{kq_1q_2}{r^3}\vec{r}; \vec{E} = \frac{kq}{r^2}\hat{r} = \frac{kq}{r^3}\vec{r}; F = qE$$

In a diagram, the direction of an electric field is represented by the direction of its arrows, while the strength of the field is represented by the proximity of the lines.

$$\lambda = \frac{Q}{r}; \sigma = \frac{Q}{A}; \rho = \frac{Q}{V}$$

$$E = \int dE = \int \frac{k dq}{r^3}\vec{r} = \int \frac{k\lambda}{r^3}\vec{r}dr$$

$$\vec{E}_{ring}(z) = \frac{kqz}{(z^2 + R^2)^{3/2}}\hat{k}$$

For a rod of length L, measured at a distance d from the close end from the rod of charge Q.

$$\vec{E}_{axis} = -\frac{kQ}{d(d-L)}\hat{i}$$

For a rod of length L, measured perpendicular to the rod at a distance d from the close end from the rod of charge Q.

$$\vec{E} = k\lambda \left[ \frac{1}{z} - \frac{1}{L^2 + z^2} \right] \hat{i} + \frac{k\lambda L}{z\sqrt{L^2 + z^2}} \hat{j}$$

$$V = k\lambda \ln \left( \frac{L + \sqrt{L^2 + d^2}}{d} \right)$$

$$\vec{E}_{arc} = \frac{k\lambda}{r} \begin{pmatrix} 2\sin(\frac{\theta}{2}) \\ 0 \end{pmatrix}$$

$$\vec{E}_{disc} = \frac{\sigma}{2\epsilon_0} \left( 1 - \frac{z}{\sqrt{z^2 + R^2}} \right)$$

For a spherical shell of radius R.

$$\vec{E} = \begin{cases} 0 & \text{if } r < R \\ \frac{kq}{r^2}\hat{r} & \text{otherwise} \end{cases}$$

If  $r < R$ ,  $\Delta V = 0$ . If  $r \rightarrow \infty$ ,  $V = 0$ .  
 Solid sphere of radius R.

$$\vec{E} = \begin{cases} \frac{kqr}{R^3} & \text{if } r < R \\ \frac{kq}{r^2}\hat{r} & \text{otherwise} \end{cases}$$

Gauss' Law

$$\Phi = \frac{q_{enc}}{\epsilon_0}; \Phi = \oint \vec{E} \cdot d\vec{A}$$

A must be a Gaussian surface. If  $\vec{E}$  is constant on the surface, it can be simplified to  $\Phi = E * A$ . Conductors in an electric field have  $\vec{E} = 0$  inside. Electrons move to ensure this. Inside,  $\Phi = 0$ .

Electrical Potential Difference

Path independent. For  $\vec{E}(x, y, z)$ :

$$\Delta V = \frac{\Delta U}{q} = - \int_i^f \vec{E} \cdot d\vec{x} = \int_i^f dV$$

Electric field lines go from more positive to more negative voltage.

Equipotential surface (ES): Surface with same V.  
 Conductors have equipotential volumes and  $\vec{E} = 0$

$$V = \frac{kq}{r} = \int \frac{k dQ}{r}; \vec{E} = -\nabla V$$

Capacitance (C)

Relationship between charged separated and potential difference.  $Q = C * \Delta V$  To find capacitance:

1. Draw a picture
2. Determine direction of  $\vec{E}$
3. Determine  $\vec{E}$  (Gauss' and determined distributions help), then  $\Delta V = - \int \vec{E} \cdot d\vec{s}$
4. Calculate C with  $C = \frac{Q}{\Delta V}$

For parallel plates,  $C = \frac{A\epsilon_0}{d}$ .

For cylindrical capacitor length L,  $C = \frac{2\pi L\epsilon_0}{\ln(b/a)}$ .

Concentric spheres of radii a and b,  $C = 4\pi\epsilon_0 \frac{ab}{b-a}$ .

Isolated sphere of radius R,  $C = 4\pi\epsilon_0 R$ .

Since  $W = q\Delta V$ ,  $\Delta U = \frac{1}{2}C*\Delta V^2 = \frac{q^2}{2C}$  (Electric Potential Energy)

$$u = \frac{1}{2}\epsilon_0 E^2 = \frac{U}{Vol}$$

A dielectric/material is in an electric field has a dielectric constant  $\kappa$ . In it,  $\epsilon_0$  is replaced with  $\kappa\epsilon_0$ .  $\kappa$  of metals is considered  $\infty$ .  $\kappa(vacuum) = 1$

If you put a dielectric in a capacitor, treat it like a network of capacitors in a creative alignment.

Add a dielectric to charged capacitor:

$$Q_\kappa = Q_0; V_\kappa < V_0; C_\kappa > C_0; U_\kappa < U_0$$

Add a dielectric to battery-connected capacitor:

$$V_\kappa = V_0; Q_\kappa > Q_0; C_\kappa > C_0; U_\kappa > U_0$$

Current

$$I = \frac{dq}{dt}$$

Ohm's Law:  $V = IR$

Junction rule: For any point on a circuit,  $I_{in} = I_{out}$

Stored charge at junction slows down  $I_{in}$  & speeds up  $I_{out}$

Current Density

For a cross-section  $\vec{A}$ ,  $dI = \vec{J} \cdot d\vec{A}$

$$\vec{J} = e * \vec{v}_d * n = \frac{\vec{E}}{\rho}$$

Circuits

Batteries keep  $\Delta V$  constant

Long end of battery diagram is + side

Series Parallel

$$\text{Capacitor } \frac{1}{C} = \sum \frac{1}{C_i} \quad C = \sum C_i$$

$$\text{Resistor } R = \sum R_i \quad \frac{1}{R} = \sum \frac{1}{R_i}$$

## Electric Dipoles

$$\begin{aligned}\vec{E} &= \begin{cases} < 0 & \text{if } -\frac{d}{2} < z < \frac{d}{2} \\ > 0 & \text{otherwise} \end{cases} \\ &= \frac{2kQd}{z^3 \left(1 - \frac{d^2}{4z^2}\right)^2} \hat{d}\end{aligned}$$

ESs are  $\perp$  to  $\vec{p}$ . In an electric field:

$$\begin{aligned}\vec{p} &= Q\vec{d} \\ \vec{\tau} &= \vec{p} \times \vec{E} \\ U &= -\vec{p} \cdot \vec{E} \\ W_{net} &= \Delta K = -\Delta U\end{aligned}$$
